Part I

Function Descriptions and Examples

Chapter 1

concat.split

The `concat.split` function takes a column with multiple values, splits the values into a list or into separate columns, and returns a new `data.frame`.

Arguments

`mode = NULL, drop.col = FALSE, fixed = FALSE`)

- **data**: the source `data.frame`.
- **split.col**: the variable that needs to be split; can be specified either by the column number or the variable name.
- **sep**: the character separating each value (defaults to ",").

***Note:** If using `structure = "compact"`, the value for `sep` can only be a single character. See the “Advanced Usage” example of how to specify multiple characters for batch conversion of columns.*

- **structure**: Can be either "compact", "expanded", or "list". Defaults to "compact".
 - "compact" creates as many columns as the maximum *length* of the resulting split. This is the most useful general-case application of this function.
 - When the input is numeric, "expanded" creates as many columns as the maximum *value* of the input data. This is most useful when converting to `mode = "binary"`.
 - "list" creates a single new column that is structurally a `list` within a `data.frame`.
- **mode**: can be either `binary` or `value` (where `binary` is default and it recodes values to 1 or NA, like Boolean data, but without assuming 0 when data is not available). This setting only applies when `structure = "expanded"`; an warning message will be issued if used with other structures.
- **drop.col**: logical (whether to remove the original variable from the output or not; defaults to TRUE).
- **fixed**: Is the input for the `sep` value *fixed*, or a *regular expression*? When `structure = "expanded"` or `structure = "list"`, it is possible to supply a regular expression containing the characters to split on. For example, to split on ",", ";", or "|", you can set `sep = ",|;|\\|"` or `sep = "[,;|]"`, and `fixed = FALSE` to split on *any* of those characters.

Examples

First load some data from a CSV stored at [github](https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/). The URL is an HTTPS, so we need to use `getURL` from `RCurl`.

```
require(RCurl)
baseURL = c("https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/")
temp = getURL(paste0(baseURL, "data/concatenated-cells.csv"))
concat.test = read.csv(textConnection(temp))
rm(temp)
```

```
# How big is the dataset?
dim(concat.test)
```

```
## [1] 48  4
```

```
# Just show me the first few rows
head(concat.test)
```

```
##      Name      Likes      Siblings      Hates
## 1   Boyd 1,2,4,5,6 Reynolds , Albert , Ortega 2;4;
## 2   Rufus 1,2,4,5,6 Cohen , Bert , Montgomery 1;2;3;4;
## 3    Dana 1,2,4,5,6      Pierce      2;
## 4  Carole 1,2,4,5,6 Colon , Michelle , Ballard 1;4;
## 5  Ramona 1,2,5,6      Snyder , Joann , 1;2;3;
## 6  Kelley 1,2,5,6      James , Roxanne , 1;4;
```

Notice that the data have been entered in a very silly manner. Let's split it up!

```
# Load the function!
# require(RCurl)
# baseURL = c("https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/")
source(textConnection(getURL(paste0(baseURL, "scripts/concat.split.R"))))
```

```
# Split up the second column, selecting by column number
head(concat.split(concat.test, 2))
```

```
##      Name      Likes      Siblings      Hates Likes_1 Likes_2 Likes_3
## 1   Boyd 1,2,4,5,6 Reynolds , Albert , Ortega 2;4;      1      2      4
## 2   Rufus 1,2,4,5,6 Cohen , Bert , Montgomery 1;2;3;4;      1      2      4
## 3    Dana 1,2,4,5,6      Pierce      2;      1      2      4
## 4  Carole 1,2,4,5,6 Colon , Michelle , Ballard 1;4;      1      2      4
## 5  Ramona 1,2,5,6      Snyder , Joann , 1;2;3;      1      2      5
## 6  Kelley 1,2,5,6      James , Roxanne , 1;4;      1      2      5
##  Likes_4 Likes_5
## 1      5      6
## 2      5      6
## 3      5      6
## 4      5      6
## 5      6     NA
## 6      6     NA
```

```
# ... or by name, and drop the offensive first column
head(concat.split(concat.test, "Likes", drop.col = TRUE))
```

```
##      Name                Siblings    Hates Likes_1 Likes_2 Likes_3 Likes_4
## 1  Boyd Reynolds , Albert , Ortega    2;4;      1      2      4      5
## 2  Rufus  Cohen , Bert , Montgomery 1;2;3;4;    1      2      4      5
## 3   Dana                Pierce      2;      1      2      4      5
## 4 Carole Colon , Michelle , Ballard    1;4;    1      2      4      5
## 5 Ramona                Snyder , Joann ,    1;2;3;    1      2      5      6
## 6 Kelley                James , Roxanne ,    1;4;    1      2      5      6
## Likes_5
## 1      6
## 2      6
## 3      6
## 4      6
## 5     NA
## 6     NA
```

The "Hates" column uses a different separator:

```
head(concat.split(concat.test, "Hates", sep = ";", drop.col = TRUE))
```

```
##      Name      Likes                Siblings Hates_1 Hates_2 Hates_3 Hates_4
## 1  Boyd 1,2,4,5,6 Reynolds , Albert , Ortega      2      4      NA      NA
## 2  Rufus 1,2,4,5,6  Cohen , Bert , Montgomery      1      2      3      4
## 3   Dana 1,2,4,5,6                Pierce      2      NA      NA      NA
## 4 Carole 1,2,4,5,6 Colon , Michelle , Ballard      1      4      NA      NA
## 5 Ramona  1,2,5,6                Snyder , Joann ,      1      2      3      NA
## 6 Kelley  1,2,5,6                James , Roxanne ,      1      4      NA      NA
## Hates_5
## 1     NA
## 2     NA
## 3     NA
## 4     NA
## 5     NA
## 6     NA
```

You'll get a warning here, when trying to retain the original values

```
head(concat.split(concat.test, 2, mode = "value", drop.col = TRUE))
```

```
## Warning: 'mode' supplied but ignored. 'mode' setting only applicable when
## structure='expanded'.
```

```
##      Name                Siblings    Hates Likes_1 Likes_2 Likes_3 Likes_4
## 1  Boyd Reynolds , Albert , Ortega    2;4;      1      2      4      5
## 2  Rufus  Cohen , Bert , Montgomery 1;2;3;4;    1      2      4      5
## 3   Dana                Pierce      2;      1      2      4      5
## 4 Carole Colon , Michelle , Ballard    1;4;    1      2      4      5
## 5 Ramona                Snyder , Joann ,    1;2;3;    1      2      5      6
## 6 Kelley                James , Roxanne ,    1;4;    1      2      5      6
## Likes_5
## 1      6
## 2      6
## 3      6
## 4      6
## 5     NA
## 6     NA
```

Try again. Notice the differing number of resulting columns

```
head(concat.split(concat.test, 2, structure = "expanded",
                  mode = "value", drop.col = TRUE))
```

```
##      Name                Siblings    Hates Likes_1 Likes_2 Likes_3 Likes_4
## 1  Boyd Reynolds , Albert , Ortega    2;4;      1      2      NA      4
## 2  Rufus  Cohen , Bert , Montgomery 1;2;3;4;      1      2      NA      4
## 3   Dana                Pierce        2;      1      2      NA      4
## 4 Carole Colon , Michelle , Ballard    1;4;      1      2      NA      4
## 5 Ramona                Snyder , Joann , 1;2;3;      1      2      NA      NA
## 6 Kelley                James , Roxanne , 1;4;      1      2      NA      NA
## Likes_5 Likes_6
## 1      5      6
## 2      5      6
## 3      5      6
## 4      5      6
## 5      5      6
## 6      5      6
```

```
# Let's try splitting some strings... Same syntax
head(concat.split(concat.test, 3, drop.col = TRUE))
```

```
##      Name    Likes    Hates Siblings_1 Siblings_2 Siblings_3
## 1  Boyd 1,2,4,5,6    2;4; Reynolds    Albert    Ortega
## 2  Rufus 1,2,4,5,6 1;2;3;4;    Cohen      Bert    Montgomery
## 3   Dana 1,2,4,5,6      2;      Pierce
## 4 Carole 1,2,4,5,6    1;4;    Colon    Michelle    Ballard

## ..$ : num 1 2 4 5 6
## ..$ : num 1 2 4 5 6
## ..$ : num 1 2 5
```

Advanced Usage

It is also possible to use `concat.split` to split multiple columns at once. This can be done in stages, or it can be all wrapped in nested statements, as follows:

```
do.call(cbind,
  c(concat.test[1],
    lapply(1:(ncol(concat.test)-1),
      function(x) {
        splitchars = c(",", " ", ";")
        concat.split(concat.test[-1][x], 1,
          splitchars[x],
          drop.col=TRUE)
      })
  )))
```

In the example above:

- The `lapply()` function is applied to each column in the `data.frame` except the first one.
- Before applying the `concat.split` function, we enter a vector of the characters on which we should split, in the same order as the columns. Here, the first two columns are separated by commas, and the third is separated by a semicolon.
- The `concat.split` function arguments can then be included as you would if splitting a single column.
- We use `do.call(cbind, ...)` to “bind” the data together by columns. Since we had dropped the first column for the `lapply` step, we add that back in at this stage.

```
# Show just the first few lines, compact structure
# Note that the split characters must be specified
# in the same order that lapply will encounter them
head(do.call(cbind,
  c(concat.test[1],
    lapply(1:(ncol(concat.test)-1),
      function(x) {
        splitchars = c(",", " ", ";")
        concat.split(concat.test[-1][x], 1,
          splitchars[x],
          drop.col=TRUE)
      })
  )))
```

```
##      Name Likes_1 Likes_2 Likes_3 Likes_4 Likes_5 Siblings_1 Siblings_2
## 1   Boyd      1      2      4      5      6   Reynolds   Albert
## 2  Rufus      1      2      4      5      6     Cohen     Bert
## 3   Dana      1      2      4      5      6     Pierce
## 4 Carole      1      2      4      5      6      Colon  Michelle
## 5 Ramona      1      2      5      6      NA     Snyder   Joann
## 6 Kelley      1      2      5      6      NA      James   Roxanne
##      Siblings_3 Hates_1 Hates_2 Hates_3 Hates_4 Hates_5
## 1   Ortega      2      4      NA      NA      NA
## 2 Montgomery      1      2      3      4      NA
## 3              2      NA      NA      NA      NA
## 4   Ballard      1      4      NA      NA      NA
## 5              1      2      3      NA      NA
## 6              1      4      NA      NA      NA
```

```
# Show just the first few lines, Boolean mode
# Note the use of a regular expression for sep
# and the setting of fixed to FALSE
```

```
head(do.call(cbind,
  c(concat.test[1],
    lapply(1:(ncol(concat.test)-1),
      function(x) {
        concat.split(concat.test[-1][x], 1,
          sep = "[,;]",
          structure = "expanded",
          fixed = FALSE,
          drop.col=TRUE)
      }
    )))
```

Chapter 2

df.sorter

The `df.sorter` function allows you to sort a `data.frame` by columns or rows or both. You can also quickly subset data columns by using the `var.order` argument.

Arguments

- `data`: the source `data.frame`.
- `var.order`: the new order in which you want the variables to appear.
 - Defaults to `names(data)`, which keeps the variables in the original order.
 - Variables can be referred to either by a vector of their index numbers or by a vector of the variable name; partial name matching also works, but requires that the partial match identifies similar columns uniquely (see examples).
 - Basic subsetting can also be done using `var.order` simply by omitting the variables you want to drop.
- `col.sort`: the columns *within* which there is data that need to be sorted.
 - Defaults to `NULL`, which means no sorting takes place.
 - Variables can be referred to either by a vector of their index numbers or by a vector of the variable names; full names must be provided.
- `at.start`: Should the pattern matching be from the start of the variable name? Defaults to “TRUE”.

NOTE: If you are sorting both by variables and within the columns, the `col.sort` order should be based on the location of the columns in the *new data.frame*, not the original `data.frame`.

Examples

```
# Load the function!
require(RCurl)
baseURL = c("https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/")
source(textConnection(getURL(paste0(baseURL, "scripts/df.sorter.R"))))

# Make up some data
set.seed(1)
dat = data.frame(id = rep(1:5, each=3), times = rep(1:3, 5),
```

```

    measure1 = rnorm(15), score1 = sample(300, 15),
    code1 = replicate(15, paste(sample(LETTERS[1:5], 3),
                                sep="", collapse="")),
    measure2 = rnorm(15), score2 = sample(150:300, 15),
    code2 = replicate(15, paste(sample(LETTERS[1:5], 3),
                                sep="", collapse="")))

To Do

- Add an option to sort ascending or descending—at the moment, not supported.

Chapter 3

multi.freq.table

The `multi.freq.table` function takes a data frame containing Boolean responses to multiple response questions and tabulates the number of responses by the possible combinations of answers. In addition to tabulating the frequency (`Freq`), there are two other columns in the output: *Percent of Responses* (`Pct.of.Resp`) and *Percent of Cases* (`Pct.of.Cases`). *Percent of Responses* is the frequency divided by the total number of answers provided; this column should sum to 100%. In some cases, for instance when a combination table is generated and there are cases where a respondent did not select any option, the *Percent of Responses* value would be more than 100%. *Percent of Cases* is the frequency divided by the total number of valid cases; this column would most likely sum to more than 100% when a basic table is produced since each respondent (case) can select multiple answers, but should sum to 100% with other tables.

Arguments

- **data**: The multiple responses that need to be tabulated.
- **sep**: The desired separator for collapsing the combinations of options; defaults to "" (collapsing with no space between each option name).
- **boolean**: Are you tabulating boolean data (see `dat` examples)? Defaults to `TRUE`.
- **factors**: If you are trying to tabulate non-boolean data, and the data are not factors, you can specify the factors here (see `dat2` examples).
 - Defaults to `NULL` and is not used when `boolean = TRUE`.
- **NAtO0**: Should NA values be converted to 0.
 - Defaults to `TRUE`, in which case, the number of valid cases should be the same as the number of cases overall.
 - If set to `FALSE`, any rows with NA values will be dropped as invalid cases.
 - Only applies when `boolean = TRUE`.
- **basic**: Should a basic table of each item, rather than combinations of items, be created? Defaults to `FALSE`.
- **dropzero**: Should combinations with a frequency of zero be dropped from the final table?
 - Defaults to `TRUE`.
 - Does not apply when `boolean = TRUE`.
- **clean**: Should the original tabulated data be retained or dropped from the final table?
 - Defaults to `TRUE`.
 - Does not apply when `boolean = TRUE`.

Examples

Boolean Data

```
# Load the function!
require(RCurl)
baseURL = c("https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/")
source(textConnection(getURL(paste0(baseURL, "scripts/multi.freq.table.R"))))
```

```
# Make up some data
set.seed(1)
dat = data.frame(A = sample(c(0, 1), 20, replace=TRUE),
                 B = sample(c(0, 1, NA), 20,
                           prob=c(.3, .6, .1), replace=TRUE),
                 C = sample(c(0, 1, NA), 20,
                           prob=c(.7, .2, .1), replace=TRUE),
                 D = sample(c(0, 1, NA), 20,
                           prob=c(.3, .6, .1), replace=TRUE),
                 E = sample(c(0, 1, NA), 20,
                           prob=c(.4, .4, .2), replace=TRUE))
```

```

Extended Examples

The following example is based on some data available from the University of Auckland's Student Learning Resources¹.

When the data are read into R, the factor labels are very long, which makes it difficult to see on the screen. Thus, in the first example that follows, the factor levels are first recoded before the multiple frequency tables are created. Additionally, the data for the binary information in the second example was coded in a common 1 = Yes and 2 = No format, but we need 0 = No instead, so we need to do some recoding there too before using the function.

```
# Get the data
library(foreign)
temp = "http://cad.auckland.ac.nz/file.php/content/files/slc/"
computer = read.spss(paste0(temp,
                             "computer_multiple_response.sav"),
                    to.data.frame=TRUE)

rm(temp)
# Preview
dim(computer)

Chapter 4

RandomNames

The `RandomNames()` function uses data from the *Genealogy Data: Frequently Occurring Surnames from Census 1990–Names Files* web page¹ to generate a `data.frame` with random names.

The Arguments

- **N**: The number of random names you want. Defaults to 100.
- **cat**: Do you want "common" names, "rare" names, names with an "average" frequency, or some combination of these? Should be specified as a character vector (for example, `c("rare", "common")`). Defaults to `NULL`, in which case all names are used as the sample frame.
- **gender**: Do you want first names from the "male" dataset, the "female" dataset, or from all available names? Should be specified as a quoted string (for example, "male"). Defaults to `NULL`, in which case all available first names are used as the sample frame.
- **MFprob**: What proportion of the sample should be male names and what proportion should be female? Specify as a numeric vector that sums to 1 (for example, `c(.6, .4)`). The first number represents the probability of sampling a "male" first name, and the second number represents the probability of sampling a "female" name. This argument is not used if only one **gender** has been specified in the previous argument. Defaults to `NULL`, in which case, the probability used is `c(.5, .5)`.
- **dataset**: What do you want to use as the dataset of names from which to sample? A default dataset is provided that can generate over 400 million unique names. See the “*Dataset Details*” section for more information.

Dataset Details

This function samples from a provided dataset of names. By default, it uses the data from the *Genealogy Data: Frequently Occurring Surnames from Census 1990–Names Files* web page. Those data have been converted to `list` named “`CensusNames1990`” containing three `data.frames` (named “`surnames`”, “`malenames`”, and “`femalenames`”) and saved as an `.RData` file named `CensusNames.RData`. The data file (approximately 615 kb) can be manually downloaded from [Github](https://github.com/mrdwab/2657-R-Functions/blob/master/data/CensusNames.RData)² and loaded to your workspace. The function will perform some basic checking to see if either the `CensusNames.RData` file or the `CensusNames1990` objects are available in your workspace or working directory. If neither is found and an internet connection is active during your R session, the function will offer you the option to automatically download the dataset and add it to your *current* session.

Alternatively, you may provide your own data in a `list` formatted according to the following specifications (see the “*myCustomNames*” data in the “*Examples*” section). *Please remember that R is case sensitive!*

¹See http://www.census.gov/genealogy/www/data/1990surnames/names_files.html

²See: <https://github.com/mrdwab/2657-R-Functions/blob/master/data/CensusNames.RData>

- This must be a named list with three items: "surnames", "malenames", and "femalenames".
- The contents of each list item is a `data.frame` with at least the following named columns: "Name" and "Category".
- Acceptable values for "Category" are "common", "rare", and "average".

Examples

```
# Load the function!
require(RCurl)
baseURL = c("https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/")
source(textConnection(getURL(paste0(baseURL, "scripts/random.names.R"))))
```

```
# Generate 20 random names
RandomNames(N = 20)
```

Using Your Own Data

As mentioned, it is possible to use your own list of names as the basis for generating the random names (though this is perhaps unnecessary, given the number of random names possible with the provided dataset). The following is an example of how your dataset must be structured. Note that the dataset name in the `dataset` argument is *not* quoted.

```
myCustomNames <- list(
  surnames = data.frame(
    Name = LETTERS[1:26],
    Category = c(rep("rare", 10), rep("average", 10), rep("common", 6))),
  malenames = data.frame(
    Name = letters[1:10],
    Category = c(rep("rare", 4), rep("average", 4), rep("common", 2))),
  femalenames = data.frame(
    Name = letters[11:26],
    Category = c(rep("rare", 8), rep("average", 4), rep("common", 4))))
str(myCustomNames)

## List of 3
## $ surnames : 'data.frame': 26 obs. of 2 variables:
## ..$ Name : Factor w/ 26 levels "A","B","C","D",...: 1 2 3 4 5 6 7 8 9 10 ...
## ..$ Category: Factor w/ 3 levels "average","common",...: 3 3 3 3 3 3 3 3 3 3 ...
## $ malenames : 'data.frame': 10 obs. of 2 variables:
## ..$ Name : Factor w/ 10 levels "a","b","c","d",...: 1 2 3 4 5 6 7 8 9 10
## ..$ Category: Factor w/ 3 levels "average","common",...: 3 3 3 3 1 1 1 1 2 2
## $ femalenames: 'data.frame': 16 obs. of 2 variables:
## ..$ Name : Factor w/ 16 levels "k","l","m","n",...: 1 2 3 4 5 6 7 8 9 10 ...
## ..$ Category: Factor w/ 3 levels "average","common",...: 3 3 3 3 3 3 3 3 1 1 ...

RandomNames(N = 15, dataset = myCustomNames)

## Gender FirstName Surnames
## 1 M a X
## 2 M j O
## 3 M i E
## 4 F q W
## 5 M j D
## 6 M g Z
## 7 F z K
## 8 F r W
## 9 F k J
## 10 F p V
## 11 M a Q
## 12 F q A
## 13 M d M
## 14 F m H
## 15 F w B
```

References

- Inspired by the online Random Name Generator (<http://random-name-generator.info/>).
- Uses data from the 1990 US Census (http://www.census.gov/genealogy/www/data/1990surnames/names_files.html)

Chapter 5

row.extractor

The `row.extractor` function takes a `data.frame` and extracts rows with the `min`, `median`, or `max` values of a given variable, or extracts rows with specific quantiles of a given variable.

Arguments

- `data`: the source `data.frame`.
- `extract.by`: the column which will be used as the reference for extraction; can be specified either by the column number or the variable name.
- `what`: options are `min` (for all rows matching the minimum value), `median` (for the median row or rows), `max` (for all rows matching the maximum value), or `all` (for `min`, `median`, and `max`); alternatively, a numeric vector can be specified with the desired quantiles, for instance `c(0, .25, .5, .75, 1)`

Examples

```
# Load the function!
require(RCurl)
baseURL = c("https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/")
source(textConnection(getURL(paste0(baseURL, "scripts/row.extractor.R"))))

# Make up some data
set.seed(1)
dat = data.frame(V1 = 1:50, V2 = rnorm(50),
                 V3 = round(abs(rnorm(50)), digits=2),
                 V4 = sample(1:30, 50, replace=TRUE))

# Get a summary of the data
summary(dat)
```

##	V1	V2	V3	V4
## Min.	: 1.0	Min. : -2.215	Min. : 0.000	Min. : 2.00
## 1st Qu.:	:13.2	1st Qu.: -0.372	1st Qu.: 0.347	1st Qu.: 8.25
## Median :	:25.5	Median : 0.129	Median : 0.590	Median :13.00
## Mean :	:25.5	Mean : 0.100	Mean : 0.774	Mean :14.80
## 3rd Qu.:	:37.8	3rd Qu.: 0.728	3rd Qu.: 1.175	3rd Qu.:20.75
## Max.	:50.0	Max. : 1.595	Max. : 2.400	Max. :29.00

```
# Get the rows corresponding to the ,min,, ,median,, and ,max, of ,V4,
row.extractor(dat, 4)
```

```

## 44 44  0.55666 0.70  5
## 37 37 -0.39429 1.06 21
## 49 49 -0.11235 1.22 14
## 34 34 -0.05381 1.52 19
## 11 11  1.51178 2.40 29
```

To Do

- Add some error checking to make sure a valid `what` is provided.

Chapter 6

sample.size

The `sample.size` function either calculates the optimum survey sample size when provided with a population size, or the confidence interval of using a certain sample size with a given population. It can be used to generate tables (`data.frames`) of different combinations of inputs of the following arguments, which can be useful for showing the effect of each of these in sample size calculation.

The Arguments

- `population`: The population size for which a sample size needs to be calculated.
- `samp.size`: The sample size.
 - This argument is only used when calculating the confidence interval, and defaults to `NULL`.
- `c.lev`: The desired confidence level. Defaults to a reasonable 95%.
- `c.int`: The confidence interval.
 - This argument is only used when calculating the sample size.
 - If not specified when calculating the sample size, defaults to 5% and a message is provided indicating this; this is also the default action if `c.int = NULL`.
- `what`: Should the function calculate the desired sample size or the confidence interval?
 - Accepted values are "sample" and "confidence" (quoted), and defaults to "sample".
- `distribution`: Response distribution. Defaults to 50%, which will give you the largest sample size.

Examples

```
# Load the function!
require(RCurl)
baseURL = c("https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/")
source(textConnection(getURL(paste0(baseURL, "scripts/sample.size.R"))))
# What should our sample size be for a population of 300?
# All defaults accepted.
sample.size(population = 300)
```

```
##   population conf.level conf.int distribution sample.size
## 1          300         95         5           50         169
```

```

# What sample should we take for a population of 300
#   at a confidence level of 97%?
sample.size(population = 300, c.lev = 97)

##   population conf.level conf.int distribution sample.size
## 1         300         97         5          50         183

# What about if we change our confidence interval?
sample.size(population = 300, c.int = 2.5, what = "sample")

##   population conf.level conf.int distribution sample.size
## 1         300         95         2.5          50         251

# What about if we want to determine the confidence interval
#   of a sample of 140 from a population of 300? A confidence
#   level of 95% is assumed.
sample.size(population = 300, samp.size = 140, what = "confidence")

##   population conf.level conf.int distribution sample.size
## 1         300         95         6.06          50         140

```

Advanced Usage

As the function is vectorized, it is possible to easily make tables with multiple scenarios.

```

# What should the sample be for populations of 300 to 500 by 50?
sample.size(population=c(300, 350, 400, 450, 500))

##   population conf.level conf.int distribution sample.size
## 1         300         95         5          50         169
## 2         350         95         5          50         183
## 3         400         95         5          50         196
## 4         450         95         5          50         207
## 5         500         95         5          50         217

# How does varying confidence levels or confidence intervals
#   affect the sample size?
sample.size(population=300,
            c.lev=rep(c(95, 96, 97, 98, 99), times = 3),
            c.int=rep(c(2.5, 5, 10), each=5))

##   population conf.level conf.int distribution sample.size
## 1         300         95         2.5          50         251
## 2         300         96         2.5          50         255
## 3         300         97         2.5          50         259
## 4         300         98         2.5          50         264
## 5         300         99         2.5          50         270
## 6         300         95         5.0          50         169
## 7         300         96         5.0          50         176
## 8         300         97         5.0          50         183
## 9         300         98         5.0          50         193
## 10        300         99         5.0          50         207
## 11        300         95        10.0          50          73
## 12        300         96        10.0          50          78
## 13        300         97        10.0          50          85
## 14        300         98        10.0          50          93
## 15        300         99        10.0          50         107

```

```
# What is are the confidence intervals for a sample of
# 150, 160, and 170 from a population of 300?
sample.size(population=300,
            samp.size = c(150, 160, 170),
            what="confidence")
```

```
## population conf.level conf.int distribution sample.size
## 1      300          95    5.67             50         150
## 2      300          95    5.30             50         160
## 3      300          95    4.96             50         170
```

Note that the use of `rep()` is required in constructing the arguments for the advanced usage examples where more than one argument takes on multiple values.

References

See the *2657 Productions News* site for how this function progressively developed¹. The `sample.size` function is based on the following formulas²:

$$ss = \frac{-Z^2 \times p \times (1-p)}{c^2}$$

$$pss = \frac{\frac{ss}{ss-1}}{1 + \frac{ss-1}{pop}}$$

Chapter 7

stringseed.sampling

The `stringseed.sampling` function is designed as a batch sampling function that allows the user to specify any alphanumeric input as the seed *per sample in the batch*.

The Arguments

- `seedbase`: A vector of seeds to be used for sampling.
- `N`: The “population” from which to draw the sample.
- `n`: The desired number of samples.
- `write.output`: Logical. Should the output be written to a file? Defaults to `FALSE`. If `TRUE`, a csv file is written with the sample “metadata”, and a plain text file is written with the details of the resulting sample. The names of the files written are “Sample frame generated on {date the script was run} .csv” and “Samples generated on {date the script was run} .txt” and will be found in your current working directory.

Examples

```
# Load the function!
require(RCurl)
baseURL = c("https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/")
source(textConnection(getURL(paste0(baseURL, "scripts/stringseed.sampling.R"))))
# We'll use a data.frame with a list of village names, the population,
# and the desired samples as our columns. The function will use the
# village names to generate a unique seed for each village before
# drawing the sample.
myListOfPlaces <- data.frame(
  villageName = c("Melakkal", "Sholavandan", "T. Malaipatti"),
  population = c(120, 130, 140),
  requiredSample = c(30, 25, 12))
myListOfPlaces

##      villageName population requiredSample
## 1      Melakkal         120              30

Part II

The Functions

Chapter 8

Where to Get the Functions

The most current source code for the functions described in this document follow. It is recommended that you *do not* copy-and-paste the functions from this document since there may be errors resulting from poorly parsed quotation marks and so on; instead, load the functions directly from the 2657 R Functions page at github.

To load the functions, you can directly source them from the 2657 R Functions page at github: <https://github.com/mrdwab/2657-R-Functions>

You should be able to load the functions using the following (replace ----- with the function name¹):

```
require(RCurl)
baseURL = c("https://raw.githubusercontent.com/mrdwab/2657-R-Functions/master/")
source(textConnection(getURL(paste0(baseURL, "scripts/-----.R"))))
```

¹The “snippets” in Part III of this document can all be loaded from a single script, `snippets.R`.

Chapter 9

concat.split

```
concat.split = function(data, split.col, sep = ",", structure = "compact",
                        mode = NULL, drop.col = FALSE, fixed = FALSE) {
  # Takes a column with multiple values, splits the values into
  # separate columns, and returns a new data.frame.
  # --data-- is the source data.frame; --split.col-- is the variable that
  # needs to be split; --structure-- the type of output that should be
  # returned, either a -compact- or -expanded- form, or a -list-
  # (defaults to -compact-). --mode-- can be either -binary- or -value-
  # (where -binary- is default and it recodes values to 1 or NA); --sep--
  # is the character separating each value (defaults to -,). --drop.col--
  # is logical (whether to remove the original variable from the output).
  #
  # === EXAMPLES ===
  #
  #   dat = data.frame(
  #     V1 = c("1, 2, 4", "3, 4, 5", "1, 2, 5", "4", "1, 2, 3, 5"),
  #     V2 = c("1;2;3;4", "1", "2;5", "3;2", "2;3;4")
  #   )
  #   dat2 = data.frame(
  #     V1 = c("Fred, John, Sue", "Jerry, Jill",
  #            "Sally, Ryan", "Susan, Amos, Ben")
  #   )
  #
  #   concat.split(dat, 1)
  #   concat.split(dat, 1, structure="expanded")
  #   concat.split(dat, 1, structure="expanded", mode = "value")
  #   concat.split(dat, 2, sep=";")
  #   concat.split(dat, "V2", sep=";", mode="value")
  #   concat.split(dat2, 1)
  #   concat.split(dat2, "V1", drop.col=TRUE)
  #   concat.split(dat2, "V1", structure="expanded", drop.col=TRUE)
  #
  # See: http://stackoverflow.com/q/10100887/1270695
  # See also: http://stackoverflow.com/a/13912721/1270695
  #
  # Check to see if split.col is specified by name or position
  if (is.numeric(split.col)) split.col = split.col
  else split.col = which(colnames(data) %in% split.col)
  #
  # Split the data

Part III

Snippets and Tips

Chapter 16

Snippets

Load All Scripts and Data Files From Multiple Directories

```
load.scripts.and.data <- function(path, pattern = list(scripts = "*.R$",
                                                       data = "*.rda$|*.Rdata$"), ignore.case=TRUE) {
  # Reads all the data files and scripts from specified directories. In
  # general, should only need to specify the directories. Specify
  # directories without trailing slashes.
  #
  # === EXAMPLE ===
  #
  #   load.scripts.and.data(c("~/Dropbox/Public",
  #                           "~/Dropbox/Public/R Functions"))

  file.sources = list.files(path, pattern=pattern$scripts,
                             full.names=TRUE, ignore.case=ignore.case)
  data.sources = list.files(path, pattern=pattern$data,
                             full.names=TRUE, ignore.case=ignore.case)
  sapply(data.sources, load, .GlobalEnv)
  sapply(file.sources, source, .GlobalEnv)
}
```

Convert a List of Data Frames Into Individual Data Frames

```
unlist.dfs <- function(data) {
  # Specify the quoted name of the source list.
  q = get(data)
  prefix = paste0(data, "_", 1:length(q))
  for (i in 1:length(q)) assign(prefix[i], q[[i]], envir=.GlobalEnv)
}
```

Example

Note that the list name must be quoted.

```
# Sample data
temp = list(A = data.frame(A = 1:2, B = 3:4),
            B = data.frame(C = 5:6, D = 7:8))
temp
```

```
## $A
##   A B
## 1 1 3
## 2 2 4
##
## $B
##   C D
## 1 5 7
## 2 6 8

# Remove any files with similar names to output
rm(list=ls(pattern="temp_"))
# The following should not work
temp_1
```

```
## Error: object 'temp_1' not found
```

```
# Split it up!
unlist.dfs("temp")
# List files with the desired pattern

Convert a Data Frame Into a List With Each Column Becoming a List Item

```
dfcols.list <- function(data, vectorize = FALSE) {
  # Specify the unquoted name of the data.frame to convert
  if (isTRUE(vectorize)) {
    dat.list = sapply(1:ncol(data), function(x) data[x])
  } else if (!isTRUE(vectorize)) {
    dat.list = lapply(names(data), function(x) data[x])
  }
  dat.list
}
```

Examples

```
# Sample data
dat = data.frame(A = c(1:2), B = c(3:4), C = c(5:6))
dat

##   A B C
## 1 1 3 5
## 2 2 4 6

# Split into a list, retaining data.frame structure
dfcols.list(dat)

## [[1]]
##   A
## 1 1
## 2 2
##
## [[2]]
##   B
## 1 3
## 2 4
##
## [[3]]
##   C
## 1 5
## 2 6

# Split into a list, converting to vector
dfcols.list(dat, vectorize=TRUE)

## $A
## [1] 1 2
##
## $B
## [1] 3 4
##
## $C
## [1] 5 6
```

Rename an Object in the Workplace

```
mv <- function (a, b) {
  # Source: https://stat.ethz.ch/pipermail/r-help/2008-March/156035.html
  anm = deparse(substitute(a))
  bnm = deparse(substitute(b))
  if (!exists(anm, where=1, inherits=FALSE))
    stop(paste(anm, "does not exist.\n"))
  if (exists(bnm, where=1, inherits=FALSE)) {
    ans = readline(paste("Overwrite ", bnm, "? (y/n) ", sep = " "))
    if (ans != "y")
      return(invisible())
  }
  assign(bnm, a, pos = 1)
  rm(list = anm, pos = 1)
  invisible()
}
```

Basic Usage

If there is already an object with the same name in the workplace, the function will ask you if you want to replace the object or not. Otherwise, the basic usage is:

```
# Rename "object_1" to "object_2"
mv(object_1, object_2)
```

Scrape Data From a Poorly Formatted HTML Page

Reformats a web page using HTML Tidy and uses the XML package to parse the resulting file. Can optionally save the reformatted page.

```
tidyHTML <- function(URL, saveTidy = TRUE) {
  require(XML)
  URL1 = gsub("/", "%2F", URL)
  URL1 = gsub(":", "%3A", URL1)
  URL1 = paste("http://services.w3.org/tidy/tidy?docAddr=",
              URL1, "&indent=on", sep = "")
  Parsed = htmlParse(URL1)
  if (isTRUE(saveTidy)) saveXML(Parsed, file = basename(URL))
  Parsed
}
```

Example

```
# Set „saveTidy„ to „TRUE„ to save the resulting tidied file
URL <- "http://www.bcn.gob.ni/estadisticas/trimestrales_y_mensuales/siec/datos/4.IMAE.htm"
temp <- tidyHTML(URL, saveTidy = FALSE)
```

“Rounding in Commerce”

R rounds to even—something that some people might not be accustomed to or comfortable with. For the more commonly known rounding rule, use this `round2` function.

```
round2 <- function(x, n = 0) {
  posneg = sign(x)
  z = abs(x)*10^n
  z = z + 0.5
  z = trunc(z)
  z = z/10^n
  z*posneg
}
```

Example

```
x = c(1.85, 1.54, 1.65, 1.85, 1.84)
round(x, 1)

## [1] 1.8 1.5 1.6 1.8 1.8

round2(x, 1)
```

```
## [1] 1.9 1.5 1.7 1.9 1.8

round(seq(0.5, 9.5, by=1))

## [1] 0 2 2 4 4 6 6 8 8 10

round2(seq(0.5, 9.5, by=1))

## [1] 1 2 3 4 5 6 7 8 9 10
```

References

cbind data.frames When the Number of Rows are Not Equal

`cbind()` does not work when trying to combine `data.frames` with differing numbers of rows. This function takes a list of `data.frames`, identifies how many extra rows are required to make `cbind` work correctly, and does the combining for you.

The function also works with nested lists by first “flattening” them using the `LinearizeNestedList` by [Akhil S Bhel](#). The first time you run the `CBIND()` function, it check your current environment to identify whether `LinearizeNestedList` is already available; if it is not, it will download and load the function from its [Gist page](#). Subsequent calls to the function in the same session will not re-download the function.

```
CBIND <- function(datalist) {
  if ("LinearizeNestedList" %in% ls(envir=.GlobalEnv) == FALSE) {
    require(devtools)
    suppressMessages(source_gist(4205477))
    message("LinearizeNestedList loaded from https://gist.github.com/4205477")
  }
  datalist <- LinearizeNestedList(datalist)
  nrows <- max(sapply(datalist, nrow))
  expandmyrows <- function(mydata, rowsneeded) {
    temp1 = names(mydata)
    rowsneeded = rowsneeded - nrow(mydata)
    temp2 = setNames(data.frame(
      matrix(rep(NA, length(temp1) * rowsneeded),
              ncol = length(temp1))), temp1)
    rbind(mydata, temp2)
  }
  do.call(cbind, lapply(datalist, expandmyrows, rowsneeded = nrows))
}
```

Examples

```
# Example data
df1 <- data.frame(A = 1:5, B = letters[1:5])
df2 <- data.frame(C = 1:3, D = letters[1:3])
df3 <- data.frame(E = 1:8, F = letters[1:8], G = LETTERS[1:8])
# Try to use cbind directly
cbind(df1, df2, df3)
```

```
## Error: arguments imply differing number of rows: 5, 3, 8
```

```
# Use our new function
```

```

Generate Random Names With an Online Service

This function uses the random name generator from the [Random Name Generator](http://random-name-generator.info/) website¹. This is included here mostly for “fun”, and to show how we can use form input parameters from some websites in our R scripts.

Note: Since there is no concept of a *seed* at the website from which these names are drawn, you should expect to get different names each time the function is run. If you want more control, but similar functionality, use the `RandomNames()` function instead.

Arguments

- `number`: How many names do you want?
- `gender`: Specify whether you want "male" names, "female" names, or "both".
- `type`: Specify whether you want "common", "average", or "rare" names.

```
randomNamesOnline <- function(number = 100, gender = "both", type = "rare") {
  gender <- tolower(gender); type <- tolower(type)
  gender <- switch(gender, both = "&g=1", male = "&g=2", female = "&g=3",
    stop("gender" must be either "male", "female", or "both",))
  type <- switch(type, rare = "&st=3", average = "&st=2", common = "&st=1",
    stop("type" must be either "rare", "average", or "common",))
  tempURL <- paste("http://random-name-generator.info/random/?n=",
    number, gender, type, sep = "", collapse = "")
  temp <- suppressWarnings(readLines(tempURL))
  temp <- gsub("\t|<li>|</ol>", "", temp[102:(102 + number - 1)])
  temp
}
```

Examples

```
randomNamesOnline(10)
```

¹See: <http://random-name-generator.info/>

```
## [1] "Rod Casper"      "Elina Escobar"      "Rodrick Vickers"
## [4] "Alejandra Townes" "Shad Barela"        "Jackson Thurston"
## [7] "Darline Greenwood" "Tera Griswold"      "Alonso Deleon"
## [10] "Junko Ferraro"

randomNamesOnline(10, gender = "both", type = "common")

## [1] "Nancy Anderson" "Jesse Hall"          "Kathleen Flores" "Larry Reed"
## [5] "Thomas Rodriguez" "Roger Garcia"        "Linda Henderson" "Nicole Ward"
## [9] "Martin Walker"   "Brandon Diaz"

randomNamesOnline(10, "male", "average")

## [1] "Alejandro Becker" "Charles Black"      "Eddie Lewis"      "Alfred Soto"
## [5] "Joseph Rodriguez" "Eugene Walton"      "Ignacio Jordan"   "Ray Payne"
## [9] "Orville Wong"     "Edgar Jimenez"
```

Use strings to set seed when generating a random sample

The `stringseed.basic()` function is a more simplified (but less robust) seed generator and random sampling function, similar to the `stringseed.sampling()` function. Unlike `stringseed.sampling()`, this function does not require loading any extra packages for generating the seed, but uses basic methods such as letter substitutions and basic numeric transformations to create some “noise” before assigning a seed.

The function was originally written for students at the Tata-Dhan Academy (and named `TDASample()`) to help them draw samples during their fieldwork. See the Appendix for a more detailed concept note on how the function works and how it was expected to be used.

```
stringseed.basic <- function(inString, N, n, toFile = FALSE) {
  # Uses string input as the basis for generating seeds before sampling

  if (is.factor(inString)) inString <- as.character(inString)
  if (nchar(inString) <= 3) stop("inString must be > 3 characters")
  string1 <- "jnt3g127rbfeqixkos 586d90pyal4chzmvwu"
  string2 <- "2dyn0uxq ovalrpksieb3fhjw584cm9t7z16g"
  instring <- chartr(string1, string2, tolower(inString))
  t1 <- sd(c(suppressWarnings(sapply(strsplit(instring, ""),
                                         as.numeric))), na.rm = TRUE)
  t2 <- c(sapply(strsplit(instring, " "), nchar))
  t3 <- c(na.omit(sapply(strsplit(instring, ""), match, letters)))
  seed <- floor(sum(t1, sd(t2), mean(t2), prod(fivenum(t3)),
                    mean(t3), sd(t3), na.rm=TRUE))

  set.seed(seed)
  temp0 <- sample(N, n)
  temp1 <- list(SeedUsed = seed, FinalSample = temp0,
               FinalSample_sorted = sort(temp0))

  rm(.Random.seed, envir=globalenv())

  if (isTRUE(toFile)) {
    cat(
      sprintf("\n\n          The sample was drawn on: %s.", Sys.time()), "\n",
      sprintf("          The seed input was: %s.", inString), "\n",
      sprintf("The total number of households was: %d.", N), "\n",
```

```

        sprintf(" The desired number of samples was: %d.", n), "\n\n\n",
        file = paste("Sample from", Sys.Date(), ".txt", collapse=""), append = TRUE)
capture.output(temp1, file = paste("Sample from", Sys.Date(), ".txt", collapse=""),
               append = TRUE)
}
message(
  sprintf("\n\n          The sample was drawn on: %s.", Sys.time()), "\n",
  sprintf("          The seed input was: ,%s,", inString), "\n",
  sprintf("The total number of households was: %d.", N), "\n",
  sprintf(" The desired number of samples was: %d.", n), "\n\n\n")
temp1
}

```

Chapter 17

Tips

Many of the following tips are useful for reducing repetitious tasks. They might seem silly or unnecessary with the small examples provided, but they can be *huge* time-savers when dealing with larger objects or larger sets of data.

Batch Convert Factor Variables to Character Variables

In the example data below, `author` and `title` are automatically converted to factor (unless you add the argument `stringsAsFactor = FALSE` when you are creating the data). What if you forgot and actually needed the variables to be in mode `as.character` instead?

Use `sapply` to identify which variables are currently factors and convert them to `as.character`.

```
dat = data.frame(title = c("title1", "title2", "title3"),
                 author = c("author1", "author2", "author3"),
                 customerID = c(1, 2, 1))

str(dat)

## 'data.frame':   3 obs. of  3 variables:
## $ title      : Factor w/ 3 levels "title1","title2",...: 1 2 3
## $ author     : Factor w/ 3 levels "author1","author2",...: 1 2 3
## $ customerID: num  1 2 1

# Left of the equal sign identifies and extracts the factor variables;
# right converts them from factor to character
dat[sapply(dat, is.factor)] = lapply(dat[sapply(dat, is.factor)],
                                     as.character)

str(dat)

## 'data.frame':   3 obs. of  3 variables:
## $ title      : chr  "title1" "title2" "title3"
## $ author     : chr  "author1" "author2" "author3"
## $ customerID: num  1 2 1
```

Using Reduce to Merge Multiple Data Frames at Once

The `merge` function in R only merges two objects at a time. This is usually fine, but what if you had several `data.frames` that needed to be merged?

Consider the following data, where we want to take monthly tables and merge them into an annual table:

```
set.seed(1)
JAN = data.frame(ID = sample(5, 3), JAN = sample(LETTERS, 3))
FEB = data.frame(ID = sample(5, 3), FEB = sample(LETTERS, 3))
MAR = data.frame(ID = sample(5, 3), MAR = sample(LETTERS, 3))
APR = data.frame(ID = sample(5, 3), APR = sample(LETTERS, 3))
```

If we wanted to merge these into a single `data.frame` using `merge`, we might end up creating several temporary objects and merging those, like this:

```
temp_1 = merge(JAN, FEB, all=TRUE)
temp_2 = merge(temp_1, MAR, all=TRUE)
temp_3 = merge(temp_2, APR, all=TRUE)
```

Or, we might nest a whole bunch of `merge` commands together, something like this:

```
merge(merge(merge(JAN, FEB, all=TRUE),
             MAR, all=TRUE),
      APR, all=TRUE)
```

However, that first option requires a lot of unnecessary typing and produces unnecessary objects that we then need to remember to remove, and the second option is not very reader-friendly—try doing a merge like that with, say, 12 `data.frames` if we had an entire year of data!

Use `Reduce` instead, simply specifying all the objects to be merged in a `list`:

```
Reduce(function(x, y) merge(x, y, all=TRUE),
       list(JAN, FEB, MAR, APR))
```

```
##   ID  JAN  FEB  MAR  APR
## 1  2    X    E    R    F
## 2  3 <NA>    F    X    D
## 3  4    V <NA>    M    Q
## 4  5    F    B <NA> <NA>
```

How Much Memory Are the Objects in Your Workspace Using?

Sometimes you need to just check and see how much memory the objects in your workspace occupy.

```
sort(sapply(ls(), function(x) {object.size(get(x))}))
```

Convert a Table to a Data Frame

Creating tables are easy and fast, but sometimes, it is more convenient to have the output as a `data.frame`. Get the `data.frame` by nesting the command in `as.data.frame.matrix`.

```
# A basic table
x <- with(airquality, table(cut(Temp, quantile(Temp)), Month))
str(x)

##  'table' int [1:4, 1:5] 24 5 1 0 3 15 7 5 0 2 ...
##  - attr(*, "dimnames")=List of 2
##    ..$      : chr [1:4] "(56,72]" "(72,79]" "(79,85]" "(85,97]"
##    ..$ Month: chr [1:5] "5" "6" "7" "8" ...
```

x

```
##           Month
##           5  6  7  8  9
## (56,72] 24  3  0  1 10
## (72,79]  5 15  2  9 10
## (79,85]  1  7 19  7  5
## (85,97]  0  5 10 14  5
```

The same table as a data.frame

```
y <- as.data.frame.matrix(x)
str(y)
```

```
## 'data.frame':    4 obs. of  5 variables:
## $ 5: int  24 5 1 0
## $ 6: int  3 15 7 5
## $ 7: int  0 2 19 10
## $ 8: int  1 9 7 14
## $ 9: int 10 10 5 5
```

y

```
##           5  6  7  8  9
## (56,72] 24  3  0  1 10
## (72,79]  5 15  2  9 10
## (79,85]  1  7 19  7  5
## (85,97]  0  5 10 14  5
```

Sample Generator for Students at the Tata-Dhan Academy

Abstract: This note¹ describes a function written to assist students at the Tata-Dhan Academy to generate random samples in a systematic and reproducible (and, thus, verifiable) manner. A common method for reproducible random samples is to use the *seed* function available in major statistics and data analysis software packages. To minimize researcher bias, even the choice of seed must be justified. The function described in this note obfuscates the seed setting process but still results in output that is reproducible. Furthermore, the seed used for generating the sample is included in the output to allow others to independently validate the results.

Many times, students need to do a pretty straightforward task of taking a random sample of households from a given village to complete their study. There are a lot of random number generators available. For instance, most scientific calculators have a feature to generate random numbers, spreadsheets often have a `RAND()` function, and student statistics or research textbooks may have a random table in their appendix. However, none of these methods are verifiable or reproducible.²

Common statistics and data analysis software (for example SPSS, Stata, and R) use the concept of a **seed** with their random number generator. These packages have their own methods for automatically setting a seed so that there are different numbers each time a function that uses a random number generator is run; this number is not readily visible to the end user. Most professional packages will also allow the user to specify the seed, in case they want to make their result reproducible, for instance if they want to share their scripts with another user to verify the output.

Following is a simple example of where using a seed is useful. Using R, we are going to draw a sample of 10 from a population of 50 twice. You'll note that the resulting samples are different. After that, we will set the seed (arbitrarily) to 1 and repeat the exercise.

```
sample(50, 10)
```

```
## [1] 33 2 42 26 39 24 25 22 45 38
```

```
sample(50, 10)
```

```
## [1] 13 41 34 24 48 2 29 9 45 40
```

¹This concept note was written on 10 December 2012 by Ananda Mahto and relates to V1.0 of the `TDASample()` function. Please consider using the `stringseed.basic()` function (which may be more up-to-date) or the `stringseed.sampling()` function (which uses a more robust method for generating seeds). Both can be found at the [2657-R-Functions Github page: https://github.com/mrdwab/2657-R-Functions](https://github.com/mrdwab/2657-R-Functions).

²It may seem counter-intuitive to want to reproduce a *random* sequence, but this is sometimes important in research settings. It is not uncommon to hear, for example, a question like “How did you ‘randomly’ select your sample?”

```
set.seed(1)
sample(50, 10)

## [1] 14 19 28 43 10 41 42 29 27 3

set.seed(1)
sample(50, 10)

## [1] 14 19 28 43 10 41 42 29 27 3
```

As can be seen, by using the `set.seed()` function in R, you are able to generate a verifiable sample.

Since there is a choice (in other words, user decision) in selecting a seed, you do still run the risk of introducing bias. An investigator who wants household 46 to be a part of their sample might, for instance, try different seeds until they get a sample that includes 46 in its selection (in this case, `set.seed(3); sample(50, 10)` would include household 46). Also, some people are simply confused by the concept of a seed and do not really want to think about what it is or why it is necessary.

Most of the students at the Tata-Dhan Academy conduct several participatory rural appraisals before getting into more traditional research methods. Of these varied methods, it is expected that the “*social mapping*” exercise would assist them in any subsequent sampling exercises they may need to do for their study. After completing a social mapping exercise, students are generally able to provide a list something like the following:

Household_ID	Head_of_Household
-----	-----
1	A Umarani
2	LB Rajkumar
3	Damodar Jena
...	...
...	...
118	Madhan Kumar
119	Ananda Mahto
120	JAN Vijayabharathi

The sampling function presented in this note makes use of this information to help students generate a reproducible random (non-stratified) sample (without replacement) of all the households without having to think about what an appropriate seed would be. The envisaged usage is that the student would enter a string, the population size they are sampling from, and the desired number of samples. The string can be anything, but for the case of reproducible analysis using available data, it is suggested that the string should be the name of the first person and the last person in the village “census” (as illustrated in the example household listing) or the village name. The social mapping exercise would also be the basis for N (the total number of households).

The TDASample() Function

The following code can be copied and pasted into an R session to make the function available to the user. For convenience, you should copy and paste the function into a plain text file, save that file to your system as “TDASample.R”, and load it by typing `source("--path/to/file--")`. For instance, if you saved the file to a folder called “Scripts” in your “C” drive, you can load it using `source("C:/Scripts/TDASample.R")`. Alternatively, if an internet connection is available, you can load the function by typing: `source("http://ideone.com/plain/BR066P")`

```
TDASample <- function(inString, N, n, toFile = FALSE) {
  if (is.factor(inString)) inString <- as.character(inString)
  if (nchar(inString) <= 3) stop("inString must be > 3 characters")
}
```

```

string1 <- "jnt3g127rbfeqixkos 586d90pyal4chzmvwu"
string2 <- "2dyn0uxq ovalrpksieb3fhjw584cm9t7z16g"
instring <- chartr(string1, string2, tolower(inString))
t1 <- sd(c(suppressWarnings(sapply(strsplit(instring, ""),
                                   as.numeric))), na.rm = TRUE)
t2 <- c(sapply(strsplit(instring, " "), nchar))
t3 <- c(na.omit(sapply(strsplit(instring, ""), match, letters)))
seed <- floor(sum(t1, sd(t2), mean(t2), prod(fivenum(t3)),
               mean(t3), sd(t3), na.rm=TRUE))

set.seed(seed)
temp0 <- sample(N, n)
temp1 <- list(SeedUsed = seed, FinalSample = temp0,
             FinalSample_sorted = sort(temp0))

rm(.Random.seed, envir=globalenv())

if (isTRUE(toFile)) {
  cat(
    sprintf("\n\n          The sample was drawn on: %s.", Sys.time()), "\n",
    sprintf("          The seed input was: ,%s,", inString), "\n",
    sprintf("The total number of households was: %d.", N), "\n",
    sprintf(" The desired number of samples was: %d.", n), "\n\n\n",
    file = paste("Sample from", Sys.Date(), ".txt", collapse=""), append = TRUE)
  capture.output(temp1, file = paste("Sample from", Sys.Date(), ".txt", collapse=""),
                 append = TRUE)
}
message(
  sprintf("\n\n          The sample was drawn on: %s.", Sys.time()), "\n",
  sprintf("          The seed input was: ,%s,", inString), "\n",
  sprintf("The total number of households was: %d.", N), "\n",
  sprintf(" The desired number of samples was: %d.", n), "\n\n\n")
temp1
}

```

Function Arguments

- **inString**: A quoted string. The name of the first person and last person from your social mapping result is recommended. For instance, using the example data provided earlier, the **inString** value for this dataset would be "A Umarani, JAN Vijayabharathi".
- **N**: The number of households. From the example above, $N = 120$.
- **n**: The desired number of samples.
- **toFile**: Logical. Should the output of your sample be written to a file? If **toFile = TRUE**, a file named "*Sample from -Date-.txt*" (where date is the current date) will be written to your working directory. The contents of this file will be appended to if further samples are run using the **TDASample()** function.

Examples

```
TDASample("A Umarani, JAN Vijayabharathi", 120, 30)
```

```
## $SeedUsed
## [1] 171640
##
```

```

## $FinalSample
## [1] 1 75 49 53 119 105 20 71 55 12 95 62 113 18 2 50 99 22 110
## [20] 46 26 85 15 54 70 118 5 83 78 60
##
## $FinalSample_sorted
## [1] 1 2 5 12 15 18 20 22 26 46 49 50 53 54 55 60 62 70 71
## [20] 75 78 83 85 95 99 105 110 113 118 119

# Manual verification. Compare results below with "FinalSample" above
set.seed(187241); sample(120, 30)

## [1] 27 23 45 32 14 54 17 56 90 101 70 105 119 118 22 72 107 78 113
## [20] 117 40 69 68 89 61 94 85 62 109 44

# Was a file written with our output?
list.files(pattern="Sample from")

## character(0)

# Nope. Nothing was written. Let,s write the output to a file.
TDASample("A Umarani, JAN Vijayabharathi", 120, 30, toFile=TRUE)

## $SeedUsed
## [1] 171640
##
## $FinalSample
## [1] 1 75 49 53 119 105 20 71 55 12 95 62 113 18 2 50 99 22 110
## [20] 46 26 85 15 54 70 118 5 83 78 60
##
## $FinalSample_sorted
## [1] 1 2 5 12 15 18 20 22 26 46 49 50 53 54 55 60 62 70 71
## [20] 75 78 83 85 95 99 105 110 113 118 119

# Check again
list.files(pattern="Sample from")

## [1] "Sample from 2012-12-15 .txt"

noquote(readLines(list.files(pattern="Sample from")[1]))

## [1]
## [2]
## [3] The sample was drawn on: 2012-12-15 17:15:43.
## [4] The seed input was: 'A Umarani, JAN Vijayabharathi'
## [5] The total number of households was: 120.
## [6] The desired number of samples was: 30.
## [7]
## [8]
## [9] $SeedUsed
## [10] [1] 171640
## [11]
## [12] $FinalSample
## [13] [1] 1 75 49 53 119 105 20 71 55 12 95 62 113 18 2 50 99 22 110
## [14] [20] 46 26 85 15 54 70 118 5 83 78 60
## [15]
## [16] $FinalSample_sorted
## [17] [1] 1 2 5 12 15 18 20 22 26 46 49 50 53 54 55 60 62 70 71
## [18] [20] 75 78 83 85 95 99 105 110 113 118 119
## [19]

```

```

# Try a different string,
# for example a seed based on a village name
TDASample("Melakkal", 120, 30)

## $SeedUsed
## [1] 6032
##
## $FinalSample
## [1] 89 35 43 26 60 83 25 75 58 101 40 104 5 30 47 53 28 103 98
## [20] 94 67 7 62 27 42 108 69 29 31 78
##
## $FinalSample_sorted
## [1] 5 7 25 26 27 28 29 30 31 35 40 42 43 47 53 58 60 62 67
## [20] 69 75 78 83 89 94 98 101 103 104 108

```

Advanced Example

It is possible to use this in a more sophisticated way, for instance to perform batch sampling provided a `data.frame` with at least the following information:

1. A column containing the information to be used as your `inString`.
2. A column containing the “population” from which to draw a sample.
3. A column containing the desired sample size.

Here is one such dataset:

```

myListOfPlaces <- data.frame(
  villageName = c("Melakkal", "Sholavandan", "T. Malaipatti"),
  population = c(120, 130, 140),
  requiredSample = c(30, 25, 12))
myListOfPlaces

##      villageName population requiredSample
## 1      Melakkal         120              30
## 2    Sholavandan         130              25
## 3 T. Malaipatti         140              12

```

To batch generate the samples, you can use `apply()`, specifying the column numbers to be used for each argument. For instance, `inString` is represented by the first column (`x[1]`), `N` by the second (`x[2]`), and `n` by the third (`x[3]`).

```

setNames(apply(myListOfPlaces, 1, function(x)
  TDASample(x[1], as.numeric(x[2]), as.numeric(x[3]))),
  myListOfPlaces[[1]])

## $Melakkal
## $Melakkal$SeedUsed
## [1] 6032
##
## $Melakkal$FinalSample
## [1] 89 35 43 26 60 83 25 75 58 101 40 104 5 30 47 53 28 103 98
## [20] 94 67 7 62 27 42 108 69 29 31 78
##

```

```
## $Melakkal$FinalSample_sorted
## [1] 5 7 25 26 27 28 29 30 31 35 40 42 43 47 53 58 60 62 67
## [20] 69 75 78 83 89 94 98 101 103 104 108
##
##
## $Sholavandan
## $Sholavandan$SeedUsed
## [1] 26909
##
## $Sholavandan$FinalSample
## [1] 31 39 119 71 56 59 63 49 44 104 24 16 79 107 85 54 125 34 105
## [20] 4 76 47 55 62 48
##

## [1] 4 16 17 27 68 75 79 93 96 99 107 120
```

How the Function Works

The function works by using various methods to generate “noise” in your `inString` and ultimately converting your `inString` to a numeric value (though in a somewhat obfuscated manner) that can be used as the seed in R. For instance, at one level, the actual string you input is changed using basic character replacement techniques. Any numeric values in the resulting string are extracted and basic functions (like taking their product, or means, or standard deviation) are applied to add further “noise”. Characters are converted to numeric values based on their position in the alphabet, and similar basic functions are applied to them as part of the “formula” for generating the seed. Once the seed is generated, the sample is drawn and displayed in a convenient format that can be used for reporting purposes.

It should be noted that the method of adding “noise” might actually not be noisy enough. At the base is simple character replacement (for example, replacing all instances of “a” with, say, “x”). Thus, using “ananda” as your `inString` will result in the same seed as using “adnana”; ideally, this would not be the case. There are methods around this, for instance using the `digest` package to convert a string to a `crc32` value and then converting it to a number to use as a seed³. However, the function shared here should be fine for most student uses, and has the advantage that no extra R packages are required for the function to run.

³A function that uses this approach is “stringseed.sampling” available at <https://github.com/mrdwab/2657-R-Functions/blob/master/scripts/stringseed.sampling.R>
